Figure 11.13: Objects filled with participating media rendered with (left) strong backward scattering ( $g = -0.7$ ) and (right) strong forward scattering ( $g = 0.7$ ). Because the light source is behind the object with respect to the viewer, forward scattering leads to more light reaching the camera in this case.

HenryGreenstein provides a PhaseFunction implementation of the Henyey-Greenstein model.

```
<<HenyeyGreenstein Declarations>>=
class HenyeyGreenstein : public PhaseFunction {
public:
    <<HenyeyGreenstein Public Methods>> @
private:
    const Float g;
};

<<HenyeyGreenstein Public Methods>>=
HenyeyGreenstein(Float g) : g(g) {}

<<HenyeyGreenstein Method Definitions>>=
Float HenyeyGreenstein::p(const Vector3f &wo, const Vector3f &wi) const {
    return PhaseHG(Dot(wo, wi), g);
}
```

The asymmetry parameter  $g$  in the Henyey-Greenstein model has a precise meaning. It is the average value of the product of the phase function being approximated and the cosine of the angle between  $\omega'$  and  $\omega$ . Given an arbitrary phase function  $p$ , the value of  $g$  can be computed as<sup>4</sup>

$$g = \int_{S^2} p(-\omega, \omega') (\omega \cdot \omega') d\omega' = 2\pi \int_0^\pi p(-\cos\theta) \cos\theta \sin\theta d\theta. \quad (11.5)$$

Thus, an isotropic phase function gives  $g = 0$ , as expected.

Any number of phase functions can satisfy this equation; the  $g$  value alone is not enough to uniquely describe a scattering distribution. Nevertheless, the convenience of being able to easily convert a complex scattering distribution into a simple parameterized model is often more important than this potential loss in accuracy.
